

## Practical 2

### Aim: SDES Brute Force Attack Simulation

#### Description:

The provided code implements a brute-force attack on the Simplified Data Encryption Standard (SDES) in Java. SDES is a symmetric-key block cipher that operates on 8-bit plaintext blocks using a 10-bit key. The brute-force approach systematically tests all 1024 possible 10-bit keys to decrypt a given ciphertext and match it with a known plaintext.

The steps in the code are as follows:

1. **Key Generation:** All possible 10-bit keys are generated iteratively.
2. **Encryption and Decryption:** The SDES algorithm is used to encrypt plaintext and decrypt ciphertext using the specified key.
3. **Matching:** Each key is tested by decrypting the ciphertext and comparing it with the known plaintext.
4. **Output:** If the correct key is found, it is printed along with the decrypted text; otherwise, a failure message is displayed after testing all keys.

#### Code:

1. BruteForceSDES.java

```
import java.util.BitSet;
```

```
public class BruteForceSDES {
```

```
    // Function to brute force the key
```

```
    public static void bruteForce(BitSet ciphertext, BitSet knownPlaintext) {  
        System.out.println("Starting brute force attack...");
```

```
        for (int i = 0; i < 1024; i++) {
```

```
            // Generate a 10-bit key from the loop index
```

```
            String binaryKey = String.format("%10s", Integer.toBinaryString(i)).replace(' ', '0');
```

```
            BitSet key = SDESEncryption.bitSetFromString(binaryKey, 10); // Use SDESEncryption
```

```
            BitSet decryptedText = SDESEncryption.decrypt(ciphertext, key); // Use SDESEncryption
```

```
            // Print each key
```

```
            System.out.print("Trying key: ");
```

```
            SDESEncryption.printBinary(key, 10); // Use SDESEncryption
```

```
            if (decryptedText.equals(knownPlaintext)) {
```

```
                System.out.println("Key found!");
```

```
                System.out.print("Key: ");
```

```

        SDESEncryption.printBinary(key, 10); // Use SDESEncryption
        System.out.print("Decrypted Text: ");
        SDESEncryption.printBinary(decryptedText, 8); // Use SDESEncryption
        return;
    }
}
System.out.println("Key not found within 1024 possibilities.");
}

public static void main(String[] args) {
    // Known key and plaintext for encryption
    BitSet key = SDESEncryption.bitSetFromString("1010000010", 10); // Use SDESEncryption
    BitSet plaintext = SDESEncryption.bitSetFromString("10111101", 8); // Use SDESEncryption

    System.out.print("Original plaintext: ");
    SDESEncryption.printBinary(plaintext, 8); // Use SDESEncryption

    BitSet ciphertext = SDESEncryption.encrypt(plaintext, key); // Use SDESEncryption
    System.out.print("Ciphertext: ");
    SDESEncryption.printBinary(ciphertext, 8); // Use SDESEncryption

    bruteForce(ciphertext, plaintext);
}
}

```

## Output:

```

• [L[$] <git:(main*)> cd "/home/rebel/Roger/College/Sem_6/Crypto_Lab
/Practical-2/" && javac BruteForceSDES.java && java BruteForceSDES

```

## Code Explanation:

### 1. Key Generation:

- All 1024 possible 10-bit keys are systematically generated by iterating through the numbers 0 to 1023.
- Each number is converted into a binary string and then into a `BitSet` representation for further use.

### 2. Encryption and Ciphertext Generation:

- The known plaintext is encrypted using a predefined 10-bit key to generate the ciphertext, simulating an encrypted message.

### 3. Brute-Force Attempt:

- Each 10-bit key is tested by attempting to decrypt the ciphertext.
- Decryption involves using the SDES algorithm, which follows the standard two-round encryption process in reverse.

### 4. Key Matching:

- The decrypted text is compared with the known plaintext for each key.
- If a match is found, the corresponding key is identified as the encryption key.

### 5. Output Results:

- If the correct key is found, the key and decrypted plaintext are displayed.
- If no match is found after testing all 1024 keys, the program outputs a failure message.

## Complexity Analysis:

### Time Complexity:

#### 1. Key Generation:

- Generating each 10-bit key involves converting the loop index into a binary string and creating a `BitSet`.
- This operation takes constant time for each key,  $O(1)$ .
- As there are 1024 keys to test, the total time for key generation is  $O(1024) = O(1)$  (constant in practical terms, as the key space size is fixed).

#### 2. Decryption Process:

- For each key, the decryption process involves:
  - **Initial Permutation (IP):** Constant time,  $O(1)$ .
  - **Two Rounds of fK:** Each round involves constant-time operations such as expansion, XOR, S-box substitutions, and permutation, making each round  $O(1)$ .
  - **Final Permutation (IP-1):** Constant time,  $O(1)$ .
- Since there are two rounds and additional permutations, the decryption process for one key is  $O(1)$ .
- Testing all 1024 keys involves repeating the decryption process 1024 times, giving a total decryption time of  $O(1024) = O(1)$ .

#### 3. Comparison:

- Comparing the decrypted text with the known plaintext is a constant-time operation,  $O(1)$ , for each key.
- Across 1024 keys, the total comparison time is  $O(1024) = O(1)$ .

#### 4. Overall Time Complexity:

- Combining the key generation, decryption, and comparison steps, the overall time complexity of the brute-force attack is  $O(1024) = O(1)$ , as the number of keys is fixed and does not grow with the input size.

### Space Complexity:

#### 1. Storage for Keys:

- The current 10-bit key being tested is stored in constant space,  $O(1)$ .

#### 2. Input and Output Storage:

- The 8-bit ciphertext and known plaintext each require constant space,  $O(1)$ .

#### 3. Intermediate Values:

- Temporary values, such as permuted data, expanded data, and S-box outputs, require constant space,  $O(1)$ .

#### 4. Overall Space Complexity:

- The brute-force attack uses a constant amount of memory regardless of the number of keys, resulting in an overall space complexity of  $O(1)$ .
